# **Dynamic Optimization**

Jesús Bueren

EUI

# Dynamic Optimization

- In this chapter we are going to characterize solutions to dynamic optimization problems
- In order to solve them, we are going to introduce discrete dynamic programming.
- Along our way, we are going to revise some mathematical concepts covered by Villanacci.
- References: The PhD Macro Book (Ch 4), Acemoglu (Ch 6), and SLP (Ch 4).

# Motivating the Recursive Formulation

### A Cake Eating Problem

- We will go over a very simple dynamic optimization problem.
- Suppose that you are presented with a cake of size  $W_1$ .
- At each point in time  $t=1,2,\ldots,T$ , you can eat some of the cake but must save the rest.
- Let  $c_t$  be your consumption at time t and  $u(c_t)$  represent the flow of utility.
- u twice differentiable, strictly increasing, strictly concave,  $\lim_{c\to 0} u'(c) = \infty$ .
- Discount factor:  $0 < \beta < 1$

# The Sequential Formulation

### A Cake Eating Problem

• The agent is solving:

$$\max_{\{c_{t}, W_{t+1}\}_{t=0}^{T}} \sum_{t=0}^{I} \beta^{t} u(c_{t})$$
s.t.  $c_{t} + W_{t+1} = W_{t} \ \forall t$ 
 $W_{T+1} \geq 0$ 

The Lagrangian associated to this problem is given by:

$$\mathcal{L} = \sum_{t=0}^{T} \beta^{t} u(c_{t}) + \sum_{t=0}^{T} \lambda_{t} (W_{t} - c_{t} - W_{t+1}) + \phi W_{T+1}$$

# The Sequential Formulation

### A Cake Eating Problem

FOCs:

$$\beta^{t} u_{c}(c_{t}) = \lambda_{t}$$

$$\lambda_{t} = \lambda_{t+1}$$

$$\lambda_{T} = \phi$$

$$\phi \geq 0 \text{ with } \phi W_{T+1} = 0 \Rightarrow \beta^{T} u_{c}(c_{t}) W_{T+1} = 0$$

$$u'(c_{t}) = \beta u'(c_{t+1}) \ \forall t \in [0, T-1]$$

$$W_{T+1} = 0$$

• With the set of T intertemporal equations (euler equations), an initial condition and a terminal condition

### A Cake Eating Problem

- In order to solve finite-horizon dynamic programming problems, we are going to proceed by backwards induction.
- For t = T, given the properties of u and the constraint, the optimal solution is given by:

$$c_T = W_T$$
$$u(c_T) = u(W_T)$$

### A Cake Eating Problem

• We define the **value function** at time T as:

$$V_T(W_T) = \max_{c_T} u(c_T)$$
$$c_T + W_{T+1} = W_T$$

The optimal cake-saving decision is thus:

$$g_T(W_T) = 0$$

and the value function is given by:

$$V_T(W_T) = u(W_T)$$

### A Cake Eating Problem

• Now let's go to t = T - 1 given that we have solved the problem for t = T and define  $V_{T-1}$ .

$$V_{T-1}(W_{T-1}) = \max_{c_{T-1}, c_T, W_T, W_{T+1}} u(c_{T-1}) + \beta u(c_T)$$
s.t.  $c_{T-1} + W_T = W_{T-1}$ 

$$c_T + W_{T+1} = W_T$$

• Given that we already we know what is optimal to do in the next period, we can simplify the problem at T-1 as:

$$V_{T-1}(W_{T-1}) = \max_{c_{T-1}, W_T} u(c_{T-1}) + \beta V_T(W_T)$$
  
s.t.  $c_{T-1} + W_T = W_{T-1}$ 

### A Cake Eating Problem

• Le's write the optimality conditions as:

$$u'(c_{T-1}) = \beta V'_T(W_T)$$
  
$$u'(c_{T-1}) = \beta u'_T(W_T)$$

- The solution coincides with the sequential formulation in the last period.
- We are in good track but what about previous periods?

### A Cake Eating Problem

• Since it's going to be useful let's first derive the value of  $V'_{T-1}(W_{T-1})$  given the optimal cake saving decision  $g_{T-1}(W_{T-1})$  obtained from the previous FOC.

$$\begin{split} V_{T-1}(W_{T-1}) &= u(W_{T-1} - g_{T-1}(W_{T-1})) + \beta V_T(g_{T-1}(W_{T-1})) \\ \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} &= u_c(c_{T-1}) - u_c(c_{T-1}) \frac{\partial g_{T-1}(W_{T-1})}{\partial W_{T-1}} + \\ & \beta \frac{\partial g_{T-1}(W_{T-1})}{\partial W_{T-1}} \frac{V_T(W_T)}{\partial W_T} \\ \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} &= u_c(c_{T-1}) + \frac{\partial g_{T-1}(W_{T-1})}{\partial W_{T-1}} \Big(\beta \frac{V_T(W_T)}{\partial W_T} - u_c(c_{T-1})\Big) \\ \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} &= u_c(c_{T-1}) \end{split}$$

### A Cake Eating Problem

• At T-2 the problem can be written as:

$$V_{T-2}(W_{T-2}) = \max_{c_{T-2}, W_{T-1}} u(c_{T-2}) + \beta V_{T-1}(W_{T-1})$$
  
s.t.  $c_{T-2} + W_{T-1} = W_{T-2}$ 

With FOCs:

$$u_c(c_{T-2}) = \beta \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} = \beta u_c(c_{T-1})$$

### A Cake Eating Problem

- Suppose for the cake-eating problem, we allow the horizon to go to infinity.
- The main advantage of an infinite horizon is that the agent problem becomes stationary: the maximization problem at date t is exactly the same as in period t+1
- Unlike in finite horizon case, we don't have a terminal condition in the cake eating problem we will thus need to impose a transversality condition:

$$\lim_{t\to\infty}\beta^t u_c(c_t)W_{t+1}=0$$

if discounted marginal utility is positive, the amount of cake needs to go to zero to rule out over-accumulation

#### A Cake Eating Problem

One can consider solving the infinite horizon sequence given by:

$$\max_{\{c_t, W_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t u(c_t)$$
s.t.  $c_t + W_{t+1} = W_t + y \ \forall \ t$ 

$$\lim_{t \to \infty} \beta^t u_c(c_t) W_{t+1} = 0$$

Written in recursive form:

$$V(W_t) = \max_{\{c_t, W_{t+1}\}} u(c_t) + \beta V(W_{t+1})$$
s.t.  $c_t + W_{t+1} = W_t + y$ 

$$\lim_{t \to \infty} \beta^t V(W_t) = 0$$
(2)

The transversality condition (2) is frequently avoided because assuming V being bounded, its is satisfied for  $\beta < 1$ .

#### A Cake Eating Problem

- Equation (1) is referred as the Bellman equation.
- It is a functional equation: the unknown represents as function.
- By FOCs:

$$u_c(c_t) = \beta \frac{\partial V(W_{t+1})}{\partial W_{t+1}}$$
(3)

• Let's define g(W) the optimal savings function associated with equation (1):

$$g(W_t) = \arg \max_{W_{t+1}} u(W_t + y - W_{t+1}) + \beta V(W_{t+1})$$

$$V(W_t) = u(W_t + y - g(W_t)) + \beta V(g(W_t))$$

### A Cake Eating Problem

Provided that g is differentiable we can now compute:

$$\frac{\partial V(W_t)}{\partial W_t} = u_c(c_t) + \frac{\partial g(W_t)}{\partial W_t} \left( \beta \frac{\partial V(W_{t+1})}{\partial W_{t+1}} - u_c(c_t) \right)$$
$$\frac{\partial V(W_t)}{\partial W_t} = u_c(c_t) \Rightarrow \frac{\partial V(W_{t+1})}{\partial W_{t+1}} = u_c(c_{t+1})$$

Then we can write equation (3) as:

$$u_c(c_t) = \beta u_c(c_{t+1})$$

### A Cake Eating Problem

- Under what conditions V exists? Is it unique?
- How to find V in the infinite horizon case?
- Is g a function or a correspondence? Is it differentiable?

# The Dynamic Programming Approach

- Buiding on the intuition gained from the cake eating problem, we now consider a more formal treatment of the dynamic programming approach to answer the previous questions.
- We begin with the nonstochastic case and then add uncertainty to the formulation.

# The Dynamic Programming Approach

- Consider the infinite horizon optimization problem of an agent with payoff function  $\tilde{\sigma}(s_t, c_t)$ .
- state vector:  $s_t$ ; control vector:  $c_t$ .
- Transition equation:  $s_{t+1} = \tilde{\tau}(s_t, c_t)$ .
- The state summarizes all the information from the past that is needed to make a forward-looking decision.
- $s \in \mathcal{S}$  and  $c \in \mathcal{C}(s)$ .
- Let  $\beta$  be the discount factor and assume  $0 < \beta < 1$ .

# The Dynamic Programming Approach

The sequential problem can be written as:

$$\max_{\{c_t\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \tilde{\sigma}(s_t, c_t) \ s.t. \ s_{t+1} = \tilde{\tau}(s_t, c_t) \ c_t \in \tilde{\mathcal{C}}(s_t)$$

 We can rewrite the problem by imposing the law of motion of the state:

$$V^*(s_0) = \max_{\{s_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \sigma(s_t, s_{t+1})$$
 s.t.  $s_{t+1} \in \mathcal{C}(s_t)$ ,

Where  $V^*$  denotes the highest possible value the the objective function can reach

• The basic idea of dynamic programming is to turn the sequential problem into a functional equation:

$$V(s) = \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta V(s')$$
(4)

- Instead of choosing a sequence  $\{s_t\}_{t=0}^{\infty}$ , we choose a policy, which determines the control s' as a function of the state s.
- Given that V appears both in both sides of the equation 4 and thus it is defined recursively.
- Equation 4 is also referred as the Bellman equation after Richard Bellman, who was the first to introduce the dynamic programming formulation.
- A solution to the functional equation is thus a fixed point.

## Math Review

#### Brouwer's Fixed Point Theorem

- Let  $\mathcal M$  be a nonempty compact (closed and bounded) convex set.
- Let T be a continuous function that maps each point  $x \in \mathcal{M}$  to itself.
- Then T has a fixed point  $x^* \in \mathcal{F}$  such that  $T(x^*) = x^*$
- More questions:
  - To which set does V belong to?
  - Does the operator defined in the functional equation map each element of that set to itself?
  - Is the fixed point unique?

## Math Review

### What is a Contraction Mapping?

• Let  $(\mathcal{M}, d)$  be a metric space where  $\mathcal{M}$  is a set and d is a metric.

A metric space is a set and a function such that for all  $x, y, z \in S$ :

- 1.  $d(x, y) \ge 0$ , with equality iff x = y
- 2. d(x, y) = d(y, x)
- $3. d(x,y) \leq d(x,z) + d(z,y)$
- Let  $T: \mathcal{M} \to \mathcal{M}$  be an function mapping  $\mathcal{M}$  into itself.
- If there exists a  $\beta \in (0,1)$  such that,

$$d(\mathit{Tz}_1, \mathit{Tz}_2) \leq \beta d(z_1, z_2) \ \forall \ z_1, z_2 \in S$$

then T is a **contraction mapping** with modulus  $\beta$ .

• In other words, a contraction mapping brings elements of the space  ${\cal M}$  uniformly closer to one another.

## Math Review

### Contraction Mapping Theorem

Let  $(\mathcal{M},d)$  be a complete metric space and suppose  $T:\mathcal{M}\to\mathcal{M}$  is a contraction mapping.

A metric space is complete if every Cauchy sequence is a convergent sequence.

- A sequence  $\{x_n\}_{n=0}^{\infty}$  is a Cauchy sequence if for all  $\epsilon > 0$  there exists an  $N \in \mathbb{N}$  such that for all I, n > N,  $d(x_I, x_n) < \epsilon$
- A sequence  $\{x_n\}_{n=0}^{\infty}$  is a convergent sequence to  $\underline{x_0 \in \mathcal{M}}$  if for all  $\epsilon > 0$ , there exist here exists an  $N \in \mathbb{N}$  such that for any n > N,  $d(x_n, x_0) < \epsilon$
- Then, T has a **unique** fixed point  $\hat{z}$  and for any  $z_0 \in \mathcal{M}$ , and any  $n \in \mathbb{N}$  we have  $d(T^n z_0, \hat{z}) \leq \beta^n d(z_0, \hat{z})$ .
- That is there exists a unique  $\hat{z} \in \mathcal{M}$  such that

$$T\hat{z} = \hat{z}$$

and regardless of the starting guess  $z_0$ , the sequence  $\{T^n z_0\}_{n=0}^{\infty}$  converges to  $\hat{z}$ .

## Match Review

#### Blackwell's Sufficient Conditions for a Contraction

- Let  $s \in \mathcal{S}$  and  $(\mathcal{M}, d)$  be the metric space where  $\mathcal{M}$  is the set of bounded function equipped with the sup norm.
- Let  $T: \mathcal{M}(s) \to \mathcal{M}(s)$  satisfying:
  - 1. Monotonicity: If  $W(s) \ge Q(s)$ , for all  $s \in S$ , then  $TW(s) \ge TQ(s)$ .
  - 2. Discounting: for any constant k there exists  $\tilde{\beta} \in [0,1)$  such that  $T(W+k)(s) \leq T(W)(s) + \beta k$ .
- Then T is a contraction.

- In order to apply the Blackwell sufficient conditions, we need V to belong to the set of bounded functions.
- For this to be true, we need some assumption on the primitive objects.

- $\sigma(s_t, s_{t+1})$  needs to be bounded so that it does not yield infinite returns: we cannot compare two choices of  $s_{t+1}$  that deliver infinite value.
- With  $\beta \in (0,1)$  and bounded  $\sigma$ , the V will be bounded for the problems that we will see in this course.
- Problems might arise in models of growth: you would need growth in the return function to be "smaller" than the rate of discounting such that discounted returns are bounded.
- This assumption will allow us to define the set of V: the set of continuous bounded functions.
- Equipped with the supremum norm forms a complete metric space.

- If  $\sigma$  is continuous and  $\mathcal C$  is nonempty and compact (closed and bounded).
  - $\Rightarrow$  Unique value function satisfying the functional equation and therefore it is possible to find V(x) by an iterative process
    - 1. Select any initial value  $V_0(s) \ \forall s \in \mathcal{S}$ .
    - 2. Define a sequence of functions:

$$V_n(x) = \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta V_{n-1}(s)$$

3. The sequence  $\{V_0, V_1, \dots, V_n\}_{n=0}^{\infty}$  converges to V

- Even if V is unique it could be that the policy associated could be a correspondence unless we put further restrictions of  $\sigma$  and C:
  - 1.  $\sigma(s, s')$ : strictly concave, continuous, and differentiable.
  - 2. C(s): convex
  - $\Rightarrow$  We have a continuous and differentiable policy function
- The Enveloppe theorem holds:

$$\frac{\partial v(s)}{\partial s} = \frac{\partial \sigma(s, s')}{\partial s}$$

## Is T a Contraction?

Blackwell's Sufficient Conditions: Monotonicity

- Let  $Q(s) \leq W(s) \ \forall s \in \mathcal{S}$ .
- Let  $\phi_Q(s)$  be the policy function obtained from:

$$\phi_Q(s) = arg \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta Q(s')$$

Then,

$$TQ(s) = \sigma(s, \phi_Q(s)) + \beta Q(\phi_Q(s)) \le \sigma(s, \phi_Q(s)) + \beta W(\phi_Q(s))$$

$$= \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta W(s') = TW(s)$$

## Is T a Contraction?

Blackwell's Sufficient Conditions: Discounting

• This property is easy to verify in the dynamic programming problem:

$$T(W+k)(s) = \max_{s' \in \mathcal{C}(s)} \sigma(s,s') + \beta(W(s')+k)$$
$$= TW(s) + \beta k$$

- In 1928 Frank Ramsey, a young mathematician, posed the problem: "How much of its income should a nation save?"
  and developed a dynamic model to answer this question.
- Economic agent (a social planner) producing output from labor and capital who must decide how to split production between consumption and capital accumulation.

#### The Planner's Problem

- Time is discrete.
- Production is given by  $y_t = f(k_t)$  where  $k_t$  is capital. f satisfies inada conditions.
- The planner's problem is given by:

$$\max_{\substack{\{c_t\}_{t=0}^{\infty}\{k_{t+1}\}_{t=0}^{\infty}}} \sum_{t=0}^{\infty} \beta^t u(c_t)$$
s.t.  $c_t + k_{t+1} \le f(k_t) + (1 - \delta)k_t \ \forall t$ 

#### The Planner's Problem

• Now let's write the planner's problem in recursive form:

$$V(k) = \max_{k' \in [0, f(k) + (1 - \delta)k]} u(f(k) + (1 - \delta)k - k') + \beta V(k')$$

• The solution is characterized by:

$$u_c(c) = \beta \frac{\partial V(k')}{\partial k'} = \beta \left( \frac{\partial f(k')}{\partial k'} + 1 - \delta \right) u_c(c')$$

#### The Planner's Problem

• In the one sector growth model we define the operator T to be:

$$TV(k) = \max_{k' \in [0, f(k) + (1 - \delta)k]} \{ u(f(k) + (1 - \delta)k - k') + \beta V(k') \}$$

- We want to argue that this operator has as unique fixed point using the contraction mapping theorem.
- Thus we are going to do it using Blackwell's sufficient conditions.

#### The Planner's Problem

Monotonicity:

Let 
$$\phi_Q(k) = \arg\max_{k' \in \Gamma(k)} u(f(k) + (1-\delta)k - k' + \beta Q(k'))$$
 if  $Q(k) \leq W(k)$ , for all  $k$  then  $TQ(k) = u(f(k) + (1-\delta)k - \phi_Q(k)) + \beta V(\phi_Q(k))$   $\leq u(f(k) + (1-\delta)k - \phi_Q(k)) + \beta W(\phi_Q(k))$   $\leq TW(k)$ 

Discounting:

$$T(V+a)(k) = \max_{k' \in \Gamma(k)} \{ u(f(k)+(1-\delta)k-k') + \beta(V(k')+a) \}$$
$$= TV(k) + \beta a$$

# Solving the problem numerically

#### Discrete State Methods

- There exists a variety of numerical methods to solve dynamic programming problems like the Ramsey problem (projection, perturbation, parameterized expectation).
- The need of numerical methods arises from the fact that dynamic programming problems generally do not have tractable closed form solutions.
- Because of their simplicity, we are going to focus on discrete-state space methods.

#### Discrete State Methods

- In this case, the value function is a finite dimensional object.
- For instance, if the state space is one dimensional and has elements  $S = s_1, s_1, \ldots, s_n$ , the value function is just a vector of n elements where each element gives the value attained by the optimal policy if the initial state of the system is  $s_n \in S$ .
- Drawback: curse of dimensionality.
  - If the the value function of an m-dimensional problem with n different points in each dimension is an array of  $n^m$  different elements and the computation time needed to search this array may be prohibitively high.

#### Value Function Iteration

- Given that Blackwell sufficient conditions hold, the can use the following pseudo-code for finding the value function:
  - 1. Make a guess for  $V_0$  for all values of capital.
  - 2. Apply the operator T and recover  $V_1 = TV_0$
  - 3. Compute distance between  $V_0$  and  $V_1$ .
    - 3.1 If  $V_1$  and  $V_0$  are close enough, stop.
    - 3.2 Otherwise set  $V_0 = V_1$  and go back to 2.
- Once the algorithm has converged, you can simulate the path for capital of an economy with an initial capital endowment.

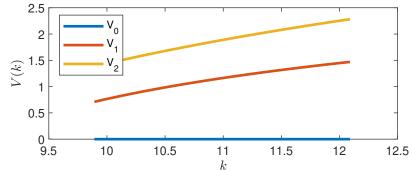

#### Value Function Iteration

- Define a grid with N points of capital between  $[\underline{k}, \overline{k}]$  around the steady state level of capital.
- Define a value of  $V_0$  for all the points in this grid. Let's say  $V_0 = 0$  for all k.
- Given this  $V_0$ , we can generate a vector for each level of capital  $k_i$  which elements are:

$$\begin{bmatrix} u(f(k_i) + (1 - \delta)k_i - k_1) + \beta V_0(k_1) \\ u(f(k_i) + (1 - \delta)k_i - k_2) + \beta V_0(k_2) \\ \vdots \\ u(f(k_i) + (1 - \delta)k_i - k_N) + \beta V_0(k_N) \end{bmatrix}$$

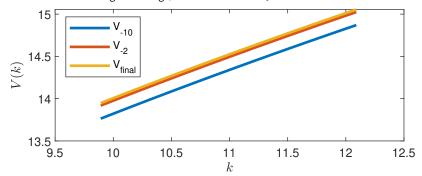

#### Value Function Iteration

- $TV_0(k)$  can be approximated by the maximum value of the elements of this vector.
- Looping through all values of  $i \in [0, N]$  we will recover  $V_1$ .
- Given  $V_1$  we can recover  $V_2$ .

#### Value Function Iteration

• We iterate until  $V_g$  and  $V_{g+1}$  are sufficiently close

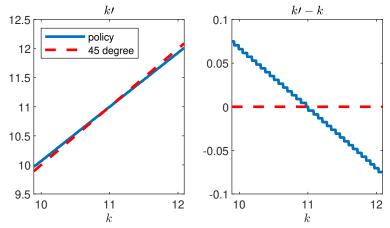

Value Function Iteration

• Now that we have V, we need to recover  $\pi(k)$  which is given by:

$$\pi(k) = \arg\max_{k'} \{u(k, k') + \beta V(k')\}$$

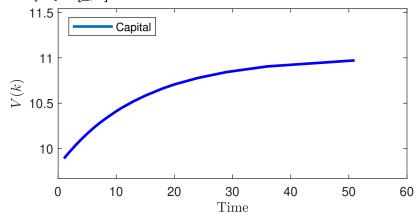

What do we aim for?

#### · A policy function:

#### Evolution of capital

• Given  $\pi(k)$  we can simulate the transition towards the steady state for any  $k_0 \in [\underline{k}, \overline{k}]$ .

# The NGM with Uncertainty

 Now, we focus on another application: the stochastic version of neoclassical growth model where shocks are going to affect firm's productivity.

$$y(z,k)=e^zf(k)$$

- We are going to assume that stochastic variables can take finitely many values.
- This restriction allows us to use Markov chains to represent uncertainty.

### The Social Planner Problem

• The recursive formulation of this problem can be written as:

$$V(k,z) = \max_{k'} \left\{ u(k,k',z) + \beta E_{z'|z}[V(k',z')] \right\}$$
  
s.t.  $k' \in \Gamma(k,z) \equiv [0, e^z f(k) + (1-\delta)k]$   
 $z' = \rho z + \epsilon, \ \epsilon \sim N(0, \sigma_{\epsilon}^2)$ 

### Discretize an AR(1) using the Tauchen Method

• Method for discretizing an AR(1) process in N points.

$$z_t = \rho z_{t-1} + \epsilon, \epsilon \sim N(0, \sigma_{\epsilon}^2)$$

- Unconditional variance:  $\sigma_z^2 = \frac{\sigma_\epsilon^2}{1 \rho^2}$
- 1. Create a (equally spaced) grid with first and last point in the grid q standard deviations away from the mean:  $z_1 = -q\sigma_z$ ,  $z_N = q\sigma_z$ 
  - ► Space between points:  $dz = \frac{z_N z_1}{N 1}$
- 2. Fill the transition matrix  $\Pi$ :

$$\Pi(z_j|z_i) = Pr\left[z_j - dz/2 \le \rho z_i + \epsilon \le z_j + dz/2\right]$$

$$= \Phi\left[\frac{z_j + dz/2 - \rho z_i}{\sigma_{\epsilon}}\right] - \Phi\left[\frac{z_j - dz/2 - \rho z_i}{\sigma_{\epsilon}}\right]$$

#### Blackwell's sufficient conditions

• Let's define the operator T over function  $V^g$  as:

$$TV^{g}(k_{t}, z_{t}) = \max_{k_{t+1}} \{u(k_{t}, k_{t+1}, z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})V^{g}(k_{t+1}, z_{t+1})\}$$

• Is operator *T* a contraction mapping? Are Blackwell's sufficient conditions satisfied?

#### Blackwell's Sufficient Conditions

• Monotonicity: If  $V(k_t, z_t) \leq W(k_t, z_t)$  for all  $k_t$  and  $z_t$ :

$$TV(k_{t}, z_{t}) = \max_{k_{t+1}} \{u(k_{t}, k_{t+1}, z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})V(k_{t+1}, z_{t+1})\}$$

$$= u(k_{t}, g_{v}(k_{t}, z_{t}), z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})V(g_{v}(k_{t}, z_{t}), z_{t+1})$$

$$\leq u(k_{t}, g_{v}(k_{t}, z_{t}), z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})W(g_{v}(k_{t}), z_{t+1}) \leq TW(k_{t}, z_{t})$$

Discounting:

$$T[V(k_t, z_t) + a]$$

$$= \max_{k_{t+1}} \{ u(k_t, k_{t+1}, z_t) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_t) (V(k_{t+1}, z_{t+1}) + a) \}$$

$$= T[V(k_t, z_t)] + \beta a$$

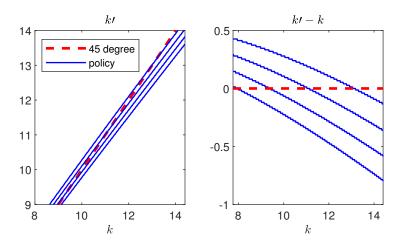

# Discrete State-Space Methods: Value Function Iteration

• Make a guess of  $V^0$  and loop over all combinations of capital and shocks and solve for:

$$V^{1}(k_{i}, z_{j}) = \max_{k' \in K} U(e^{z_{j}} f(k_{i}) + (1 - \delta)k_{i} - k') + \beta \sum_{z'} \Pi(z'|z_{j}) V^{0}(k', z')$$

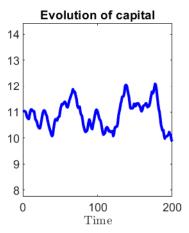

• If  $V^1$  and  $V^0$  are different, then set  $V^0 = V^1$  and iterate until convergence.

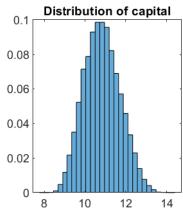

# Policy function

#### Simulation

 Now we don't reach an steady state level of capital but a stationary distribution for capital.

### The Social Planner

#### Characterizing the Solution

Taking first-order conditions from recursive formulation we get:

$$\begin{split} \frac{\partial u(k,k',z)}{\partial k'} + \beta E_{z'|z} \frac{\partial V(k',z')}{\partial k'} &= 0\\ u_c(k,k',z) &= \beta E_{z'|z} \Big[ (e^{z'}f'(k') + 1 - \delta) u_c(k',k'',z') \Big] \end{split}$$
